*Core strength is a term many of us have heard. And while we might be able to identify muscles like the abdominals and gluteals, the term "core strength" is a bit harder to define. In this class, we'll look at the biomechanics of the core and its implications to activities from walking, golfing to making your world-famous pumpkin pie.*

*We'll also make the case that while your typical 'googlable' exercises like side planks and bridges are tremendously useful, they don't always address the neurophysiological causes of your "weak core." In this 2-part course, learn the cause & effects of a weak core as well as practical "food for thought" as you head into your next exercise class.*

# Core Principles: from the back to beyond

# Core strength training for patients with chronic low back pain

- Through core strength training, patients with chronic low back pain can strengthen their deep trunk muscles …

- …All of the core strength training strategies examined in this study assist in the alleviation of chronic low back pain

J Phys Ther Sci. 2015 Mar; 27(3): 619–622.

# Lumbopelvic Core Stabilization Exercise and Pain Modulation Among Individuals with Chronic Nonspecific Low Back Pain.

- **BACKGROUND:**
- Lumbopelvic stabilization training (LPST) may provide therapeutic benefits on pain modulation in chronic nonspecific low back pain conditions. This study aimed to examine the effects of LPST on pain threshold and pain intensity in comparison with the passive automated cycling intervention and control intervention among patients with chronic nonspecific low back pain.

**CONCLUSIONS:**

- Lumbopelvic stabilization training may provide therapeutic effects by inducing pain modulation through an improvement in the pain threshold and reduction in pain intensity. LPST may be considered as part of the management programs for treatment of chronic low back pain.

**Pain** Pract. 2017 Nov;17(8):1008-1014. doi: 10.1111/papr.12552. Epub 2017 Feb 25.

# Core Stability Exercise Versus General Exercise for Chronic Low Back Pain

- A meta-analysis of core stability exercise versus general exercise for chronic low back pain.

- Clinical Question: Is core stability exercise more effective than general exercise in the treatment of patients with nonspecific low back pain (LBP)?

**CONCLUSIONS:**
In the short term, core stability exercise was more effective than general exercise for decreasing pain and increasing back-specific functional status in patients with LBP.

J Athl Train. 2017 Jan;52(1):71-72. doi: 10.4085/1062-6050-51.11.16. Epub 2016 Nov 16

# Does a core stabilization exercise program have a role on shoulder rehabilitation? A comparative study in young females

- The aim of core stabilization training is to ensure appropriate muscular balance around the lumbo-pelvic-hip complex, creating a rigid cylinder against body perturbations, while allowing a stable base for accurate movement control.

- Our study showed that six-week core stabilization exercise program had a significant positive effect on the shoulder MVIC strength. This result may support the use of core stabilization exercises in the early periods of shoulder rehabilitation when the shoulder muscle strengthening exercises are painful.

Turk J Phys Med Rehabil. 2018 Dec; 64(4): 328–336.

# Is core stability a risk factor for lower extremity injuries in an athletic population? A systematic review.

**OBJECTIVES:**

- To research and summarize the literature regarding the role of core stability as a risk factor in the development of lower extremity injuries in an athletic population.

**RESULTS:**

- Nine articles were included in the systematic review. Various components of core stability were found to be related to lower extremity musculoskeletal injuries in healthy athletic populations.

- Core strength, core proprioception and neuromuscular control of the core were found to be a risk factor in the development of lower extremity injuries. However, conflicting evidence was found for core endurance as a risk factor for lower extremity injuries.

**CONCLUSION:**

- Deficits in various aspects of **core stability** were identified as potential risk factors for lower extremity injuries. As such, **core stability** needs to be considered when screening athletes.

- **It is a timing issue**

# Transversus Abdominis Activation and Timing Improves Following Core Stability Training: a Randomized Trial

- Patients with non-specific low back pain (LBP) often present with a decrease in transversus abdominis (TrA) muscle activation and delayed onset of contraction with extremity movements, potentially contributing to recurrent LBP.

- Core stability is required for extremity movement and if the timing of when the TrA contracts is not corrected patients may continue to experience LBP.

- TrA activation and timing were altered following a four-week core stability program in people with and without LBP. Clinicians should consider incorporating these exercises for improving the function of the TrA.

# Postural and respiratory functions of the pelvic floor muscles

**AIMS:** Due to their contribution to modulation of intra-abdominal pressure (IAP) and stiffness of the sacroiliac joints, the pelvic floor muscles (PFM) have been argued to provide a contribution to control of the lumbar spine and pelvis. Furthermore, as IAP is modulated during respiration this is likely to be accompanied by changes in PFM activity.

**METHODS:** In order to evaluate the postural and respiratory function of the PFM, recordings of anal and vaginal electromyographic activity (EMG) were made with surface electrodes during single and repetitive arm movements that challenge the stability of the spine. EMG recordings were also made during respiratory tasks.

**RESULTS:** EMG activity of the PFM was increased in advance of deltoid muscle activity as a component of the pre-programmed anticipatory postural activity. This activity was independent of the direction of arm movement.

**CONCLUSIONS:**

- This study provides evidence that the PFM contribute to both postural and respiratory functions.

Neurourol Urodyn 2007;26(3):362-71

# Postural activity of the pelvic floor muscles is delayed during rapid arm movements in women with stress urinary incontinence.

- The aim of this study was to determine whether postural activity of the pelvic floor (PF) and abdominal muscles differs between continent and incontinent women during rapid arm movements that present a postural challenge to the trunk.

- Electromyographic activity (EMG) of the PF, abdominal, erector spinae (ES), and deltoid muscles was recorded with surface electrodes.
  - During rapid shoulder flexion and extension, PF EMG increased before that of the deltoid in continent women, but after the deltoid in incontinent women ($p = 0.002$).
  - In many incontinent women, PF EMG decreased before the postural activation.

- These findings would be expected to have negative consequences for continence and lumbopelvic stability in women with incontinence.

Int Urogynecol J Pelvic Floor Dysfunct. 2007 Aug;18(8):901-11. Epub 2006 Dec 1.

# Pelvic floor muscle exercise for chronic low back pain

**OBJECTIVE:**

- To assess the effect of pelvic floor muscle exercise in patients with chronic low back pain.

**METHODS:**

- Adults (aged ≥ 18 years) with chronic low back pain (with or without radiculopathy) were randomized to undergo either routine treatment (ultrasonography, short wave diathermy and lumbar strengthening exercises; control group) or routine treatment with pelvic floor exercises (intervention group) for 24 weeks. Pain, disability (Oswestry Disability Index [ODI] score) and trunk muscle function were assessed at baseline and after completion of treatment.

**CONCLUSION:**

- Pelvic floor exercise in combination with routine treatment provides significant benefits in terms of pain relief and disability over routine treatment alone.

J Int Med Res. 2013 Feb;41(1):146-52. doi: 10.1177/0300060513475383. Epub 2013 Jan 23.

# Outline

1. **Why it matters**

2. **Anatomy:**
   - **Basic**
   - **Extended**

3. **Neuromechanics**
   - **What is a “weak” core ?**
     - **Abdominal muscles**
     - **Pelvic floor**
     - **Diaphragm**

4. Wiring of the nervous system

# Summary of the core

1. Transverse abdominis is always the 1st muscle to contract

2. This is coupled with simultaneous activation of the pelvic floor

3. Respiration and abdominal/pelvic activity are intimately linked.

4. A disruption in any single variable causes a domino effect of biomechanical demise.

# Deeper thinking

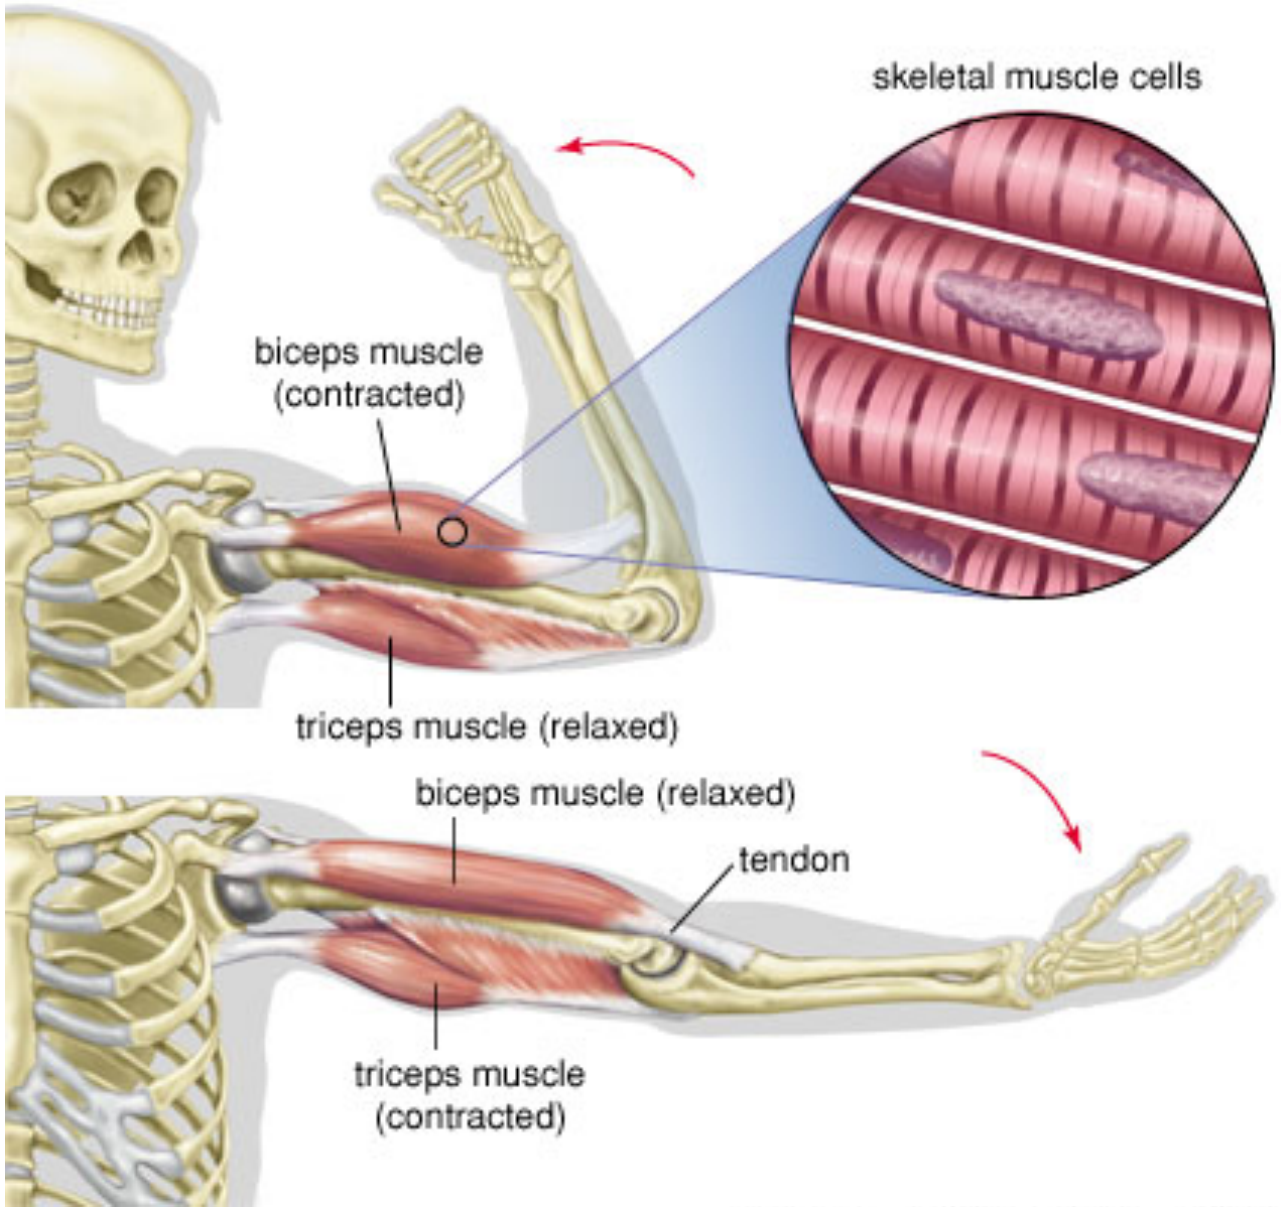
1. **You must think of muscles in pairs**
   - When one muscle "talks" the other tends to quiet down … in an open chain
   - In a closed chain, we see patterns of co-contraction to stabilize the joint

2. When any joint moves, there is a constellation of events to stabilize structures that are proximal
   - This is where we fail. The problem is generally poor stability… not a loss in ROM

3. There are predictable (but not absolute) patterns of decline

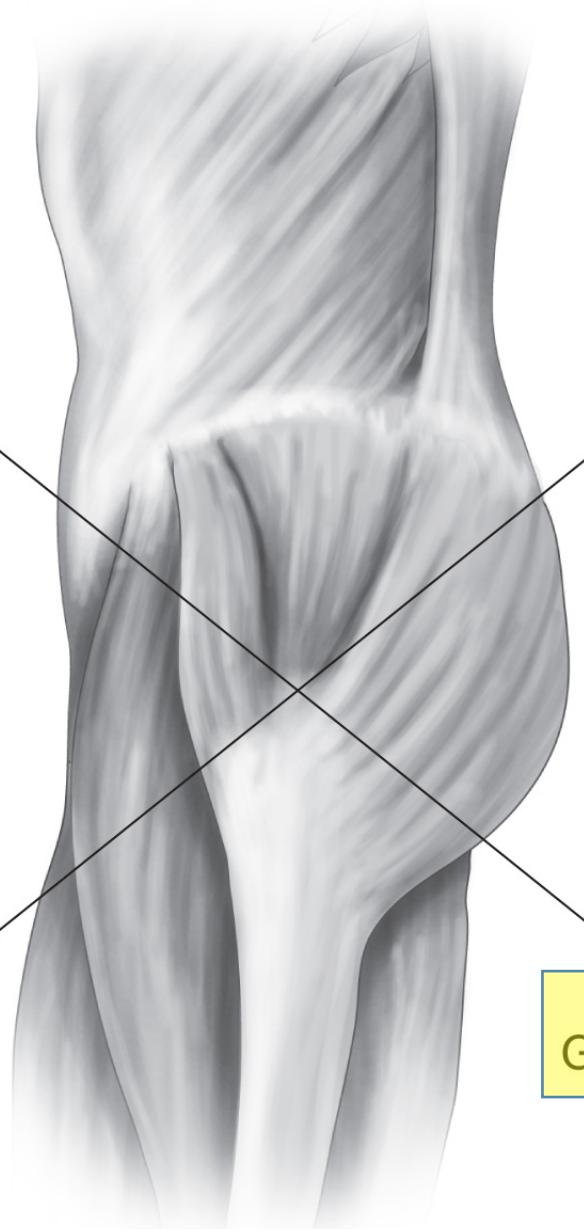
4. Our body is strongly predisposed to flex, internally rotate and adduct

- Does the biceps talk to the triceps?



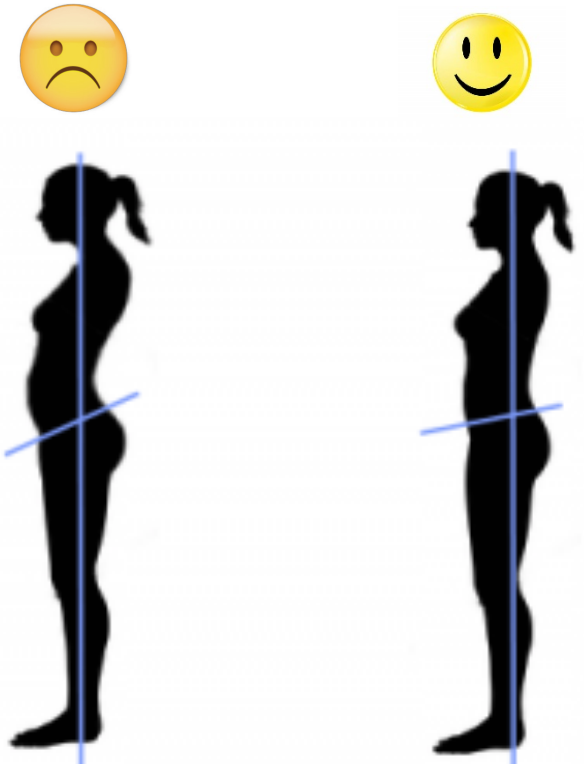
Weak:
Abdominals

Tight:
Thoracolumbar
extensors



Tight:
Hip flexors

Weak:
Gluteus maximus



# What does this mean?

1. There is more than meets the eye with a “tight muscle”
2. A “tight muscle” is usually part of a larger pattern
3. This pattern can be either biomechanically or neurologically driven.  Often, there is a duality of cause and effect.

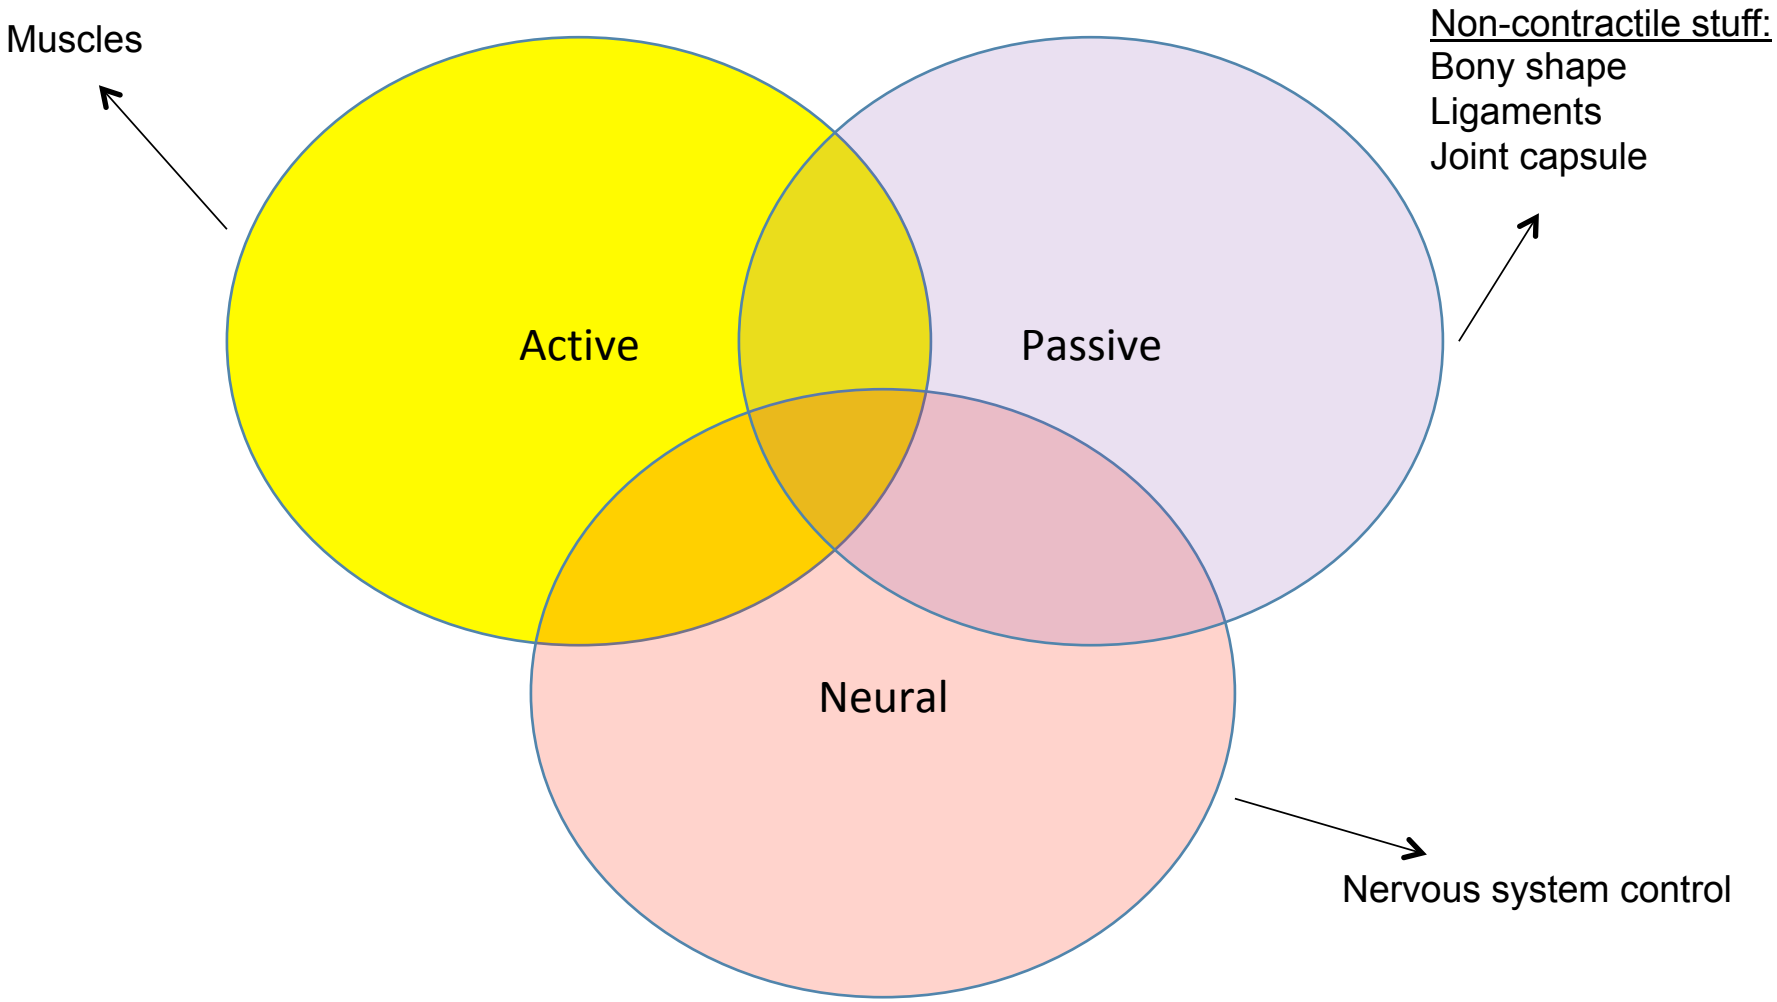
…dumb pieces of flesh that only do what they're told to do!

# Mechanisms of Core Stability



# Core strengthening

- Exercise of the core musculature is more than trunk strengthening. In fact, motor relearning of inhibited muscles may be more important than strengthening in patients with LBP.

- The overload principle advocated in sports medicine is a nemesis in the back. In other words, the progressive resistance strengthening of some core muscles, particularly the lumbar extensors, may be unsafe to the back. In fact, many traditional back strengthening exercises may also be unsafe.

# The importance of sensory-motor control in providing core stability: implications for measurement and training.

- A low level of co-contraction of the trunk muscles is important for core stability. It provides a level of stiffness, which gives sufficient stability against minor perturbations.

- It appears that most trunk muscles, both the local and global stabilization system, must work coherently to achieve core stability. The contributions of the various trunk muscles depend on the task being performed. In the search for a precise balance between the amount of stability and mobility, the role of sensory-motor control is much more important than the role of strength or endurance of the trunk muscles.

- Most importantly, a significant correlation was found between poor balance performance in a sitting balance task and delayed firing of the trunk muscles during sudden perturbation. **It was suggested that both phenomena are caused by proprioceptive deficits.**

# Reorganization of the motor cortex is associated with postural control deficits in recurrent low back pain

Many people with recurrent low back pain (LBP) have deficits in postural control of the trunk muscles and this may contribute to the recurrence of pain episodes. However, the neural changes that underlie these motor deficits remain unclear. As the motor cortex contributes to control of postural adjustments, the current study investigated the excitability and organization of the motor cortical inputs to the trunk muscles in 11 individuals with and without recurrent LBP.

EMG activity of the deep abdominal muscle, transversus abdominis (TrA), was recorded bilaterally using intramuscular fine-wire electrodes. Postural control was assessed as onset of TrA EMG during single rapid arm flexion and extension tasks. Motor thresholds (MTs) for transcranial magnetic stimulation (TMS) were determined for responses contralateral and ipsilateral to the stimulated cortex.

These findings provide preliminary evidence of reorganization of trunk muscle representation at the motor cortex in individuals with recurrent LBP, and suggest this reorganization is associated with deficits in postural control.

Brain. 2008 Aug;131(Pt 8):2161-71. doi: 10.1093/brain/awn154. Epub 2008 Jul 18.

# Differences in brain processing of proprioception related to postural control in patients with recurrent non-specific low back pain and healthy controls

- Patients with non-specific low back pain (NSLBP) show an impaired postural control during standing and a slower performance of sit-to-stand-to-sit (STSTS) movements. Therefore, we investigated brain activity during ankle and back proprioceptive processing by applying local muscle vibration during functional magnetic resonance imaging in 20 patients with NSLBP and 20 controls.

- However, the relationship between brain activity during proprioceptive processing and behavioral indices of proprioceptive use differed significantly between NSLBP and healthy control groups….

- These findings suggest that functional brain changes during proprioceptive processing in patients with NSLBP may contribute to their postural control impairments.

- …. However, future studies are needed to clarify the cause-effect relationship between functional brain changes and NSLBP, and to examine which interventions could aid in normalizing brain changes and postural control in this population.

NeuroImage:Clinical 23 (2019) 101881

# Influence of paravertebral muscles training on brain plasticity and postural control in chronic low back pain

- Isometric activation (ISOM) of deep multifidi muscles (MF) can influence postural adjustments and primary motor cortex (M1) function in chronic low back pain (CLBP).

- Changes of corticospinal excitability and of MF-S postural adjustments suggest that ISOM better influenced brain plasticity.

- This original study presents how motor control exercises can influence brain plasticity and postural control in chronic low back pain. This knowledge will impact on the decision of clinicians to prescribe specific exercises with a view of improving motor control in this musculoskeletal condition.

Scand J of Pain Vol 12, July 2016, 74-83

# Neuroplasticity of Sensorimotor Control in Low Back Pain.

- Low back pain (LBP) is an important medical and socioeconomic problem. Impaired sensorimotor control has been suggested to be a likely mechanism underlying development and/or maintenance of pain. Although early work focused on the structural and functional abnormalities within the musculoskeletal system, **in the past 20 years there has been an increasing realization that patients with LBP might also have extensive neuroplastic changes within the central nervous system.**

- Neuroplastic changes may be addressed by top-down cognitive-based interventions and bottom-up physical interventions. An integrated clinical approach that combines contemporary pain neuroscience education, cognition-targeted sensorimotor control, and physical or function-based treatments may lead to better outcomes in patients with recurrent and persistent LBP.

- This approach will need to consider variation among individuals, as no single finding/mechanism is present in all individuals, and no single treatment that targets neuroplastic changes in the sensorimotor system is likely to be effective for all patients with LBP.

J Orthop Sports Phys Ther. 2019 Jun;49(6):402-414. doi: 10.2519/jospt.2019.8489.

# A Modern Neuroscience Approach to Chronic Spinal Pain: Combining Pain Neuroscience Education With Cognition-Targeted Motor Control Training

- Chronic spinal pain (CSP) is a severely disabling disorder, including nontraumatic chronic low back and neck pain, failed back surgery, and chronic whiplash-associated disorders. Much of the current therapy is focused on input mechanisms (treating peripheral elements such as muscles and joints) and output mechanisms (addressing motor control), while there is less attention to processing (central) mechanisms. **In addition to the compelling evidence for impaired motor control of spinal muscles in patients with CSP, there is increasing evidence that central mechanisms (ie, hyperexcitability of the central nervous system and brain abnormalities) play a role in CSP.**

- Hence, treatments for CSP should address not only peripheral dysfunctions but also the brain. Therefore, a modern neuroscience approach, comprising therapeutic pain neuroscience education followed by cognition-targeted motor control training, is proposed.

# Let’s briefly change gears and step away from the core

# Stress !

From a combined neurobiological and **evolution**-theoretical perspective, the stress response is a subcortically subserved response to uncertainty that is not 'generated' but 'default': the stress response is 'always there' but as long as safety is perceived, the stress response is under tonic prefrontal **inhibition**, reflected by high vagally mediated heart rate variability.

Uncertainty of safety leads to disinhibiting the default stress response, even in the absence of threat. Due to the stress response's survival value, this 'erring on the side of caution' is passed to us via our genes. Thus, intolerance of uncertainty is not acquired during the life cycle, but is a given property of all living organisms, only to be alleviated in situations of which the safety is learned. When the latter is deficient, generalized unsafety ensues, which underlies chronic anxiety and stress and their somatic health risks, as well as other highly prevalent conditions carrying such risks, including loneliness, obesity, aerobic unfitness and old age.

… removal of prefrontal inhibition “permits” rather than “causes” an increase in physiological activity (dishinhibition)

Brosschot, J. F., Verkuil, B., & Thayer, J. F. (2016). The default response to uncertainty and the importance of perceived safety in anxiety and stress: An evolution-theoretical perspective. *Journal of Anxiety Disorders, 41,* 22–34. https://doi.org/10.1016/j.janxdis.2016.04.012
